National Standard

approval have been met by the standards developer.

Consensus is established when, in the judgment of the ANSI Board of Standards Review, substantial agreement has been reached by directly and materially affected interests. Substantial agreement means much more than a simple majority, but not necessarily unanimity. Consensus requires that all views and objections be considered, and that a concerted effort be made toward their resolution.

The use of American National Standards is completely voluntary; their existence does not in any respect preclude anyone, whether he has approved the standards or not, from manufacturing, marketing, purchasing, or using products, processes, or procedures not conforming to the standards.

The American National Standards Institute does not develop standards and will in no circumstances give an interpretation of any American National Standard. Moreover, no person shall have the right or authority to issue an interpretation of an American National Standard in the name of the American National Standards Institute. Requests for interpretations should be addressed to the secretariat or sponsor whose name appears on the title page of this standard.

CAUTION NOTICE: This American National Standard may be revised or withdrawn at any time. The procedures of the American National Standards Institute require that action be taken periodically to reaffirm, revise, or withdraw this standard. Purchasers of American National Standards may receive current information on all standards by calling or writing the American National Standards Institute.

and the following five paragraphs are the original foreword as it appeared in that document.)

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75% of the member bodies casting a vote.

International Standard ISO 6 was prepared by Technical Committee ISO/TC 42, *Photography*.

This second edition cancels and replaces the first edition (ISO 6: 1981), which has been technically revised.

Annexes A and B of this International Standard are for information only.

Suggestions for improvement of this standard will be welcome. They should be sent to the National Association of Photographic Manufacturers, Inc., 550 Mamaroneck Avenue, Suite 307, Harrison, NY 10528-1612.

This standard was processed and approved for submittal to ANSI by NAPM Technical Committee IT2 on Image Evaluation. Committee approval of the standard does not necessarily imply that all committee members voted for its approval. At the time this standard was approved, the IT2 Committee had the following members:

William F. Voglesong, Chairman
Kay E. Dodds, Vice-Chairman
Charles G. Saleski, Secretary

Black-and-white films will generally provide excellent results in several different developers and processing conditions. At the same time, it is realized that the speed of a film depends on the process used. Therefore, this International Standard specifies a method for determining the photographic speed of film/process combinations. This means a particular film may have several ISO speeds associated with it depending on the processes used. For this reason, it is important that manufacturers indicate the processing conditions for which ISO speed values are quoted.

This International Standard recognizes that black-and-white films do not generally have a unique speed if several different processes are recommended. This conflicts with the tradition of associating a specific speed value with a particular product. In the future, the process used for determining speed values should be unequivocally described to avoid misinterpretation. Since users often do not know how these films will be processed, manufacturers have an obligation to provide a speed value for this situation which will ensure good results. Usually they will take advantage of the overexposure tonal latitude of the film and give it a conservative speed value to protect users from underexposure effects in case the film is put through a process which yields low speed.

It is recognized that the speed at which a film can be exposed is dependent on the extent of development, scene luminance range, subject matter, printing paper, etc. This International Standard specifies that film/process speed is determined when the film is processed to obtain a specified contrast level. The relative ISO speed ranking of various films in different process systems will generally differ. The ISO speeds will provide correct exposures for average scenes with exposure meters conforming to ISO 2720 or ISO 2721 when the film is processed as specified in this International Standard.

American National Standard
for Photography –

Black-and-White Pictorial Still Camera Negative Film/Process Systems – Determination of ISO Speed

1 Scope

This International Standard specifies the method for determining the ISO speed of black-and-white negative camera films used for pictorial still photography.

This International Standard applies to films processed in conventional chemicals and equipment, but also to those processed using special procedures such as those involving activators or heat for development

This International Standard does not apply to motion-picture, aerial photography, graphic arts, radiographic or micrographic applications, nor to negatives produced in diffusion transfer systems.

2 Normative references

The following standards contain provisions which, through reference in this text, constitute provisions of this International Standard. At the time of publication, the editions indicated were valid. All standards are subject to revision, and parties to agreements based on this International Standard are encouraged to investigate the possibility of applying the most recent editions of the standards indicated below. Members of IEC and ISO maintain registers of currently valid International Standards.

ISO 5-2:1991, *Photography — Density measurements — Part 2: Geometric conditions for transmission density.*

ISO 5-3:1984, *Photography — Density measurements — Part 3. Spectral conditions.*

ISO 7589:1984, *Photography — Illuminants for sensitometry — Specifications for daylight and incandescent tungsten.*

3 Definitions

For the purposes of this International Standard, the following definitions apply.

3.1 exposure, H : The time integral of illuminance on the film, measured in lux seconds.

Amounts of exposure are often expressed in logarithmic terms ($\log_{10}H$).

3.2 speed: A quantitative measure of the response of the photographic material to radiant energy for the specified conditions of exposure, processing and image measurement.

4 Sampling and storage

In determining the ISO speed of a product, it is important that the evaluated samples yield the average results obtained by users. This will require evaluating several different batches periodically under the conditions specified in this International Standard. Prior to evaluation, the samples shall be stored according to the manufacturers' recommendations for a length of time to simulate the average age at which the product is normally used. Several independent evaluations shall be made to ensure the proper calibration of equipment and processes. The basic objective in selecting and storing samples as described above is to ensure the film characteristics are representative of those obtained by a photographer at the time of use.

5 Test method

5.1 Principle

Samples are exposed and processed as specified below. Density measurements are obtained from the resultant images to produce a sensitometric curve from which values are taken and used to determine ISO speed.
